# AN ALGORITHM FOR SOLVING VECTOR OP TIMIZATION ROBLEMS WITH PARAMETERS IN BOTH THE OBJECTIVE FUNCTIONS AND THE CONSTRAINTS BY USING INTERACTIVE APPROACHES 

Abou- Zaid H. El-Banna*<br>* Ass, Prof. of Pure Mathematies, Faculty of Science, Tanta university, Tanta-<br>Egypt.

#### Abstract

In this work, an algoritihm for solving vector optimization problems with parameters in both the objective functions and the constraints is introduced. An interactive approach is used for this algorithm as the surrogat worth trade-off method, Also the modified Hybrid approach which combines the characteristics of both generalized Tcheby-cheff norm and the K-th objective I-consiraints problem is used to scalarize the vector optimization problem. In this work also, the basic notions as the set of feasible paramerers, the solvability set and the stability set of the first kind are redefined for this problem, and the stability set is determined by using this algorithm, An example is given to clarify this algorthim.

INTRODUCTION
In earler work Nozidca et al. (5) and Osman et al. (6,7,8,9) gave notion of the stability set of the first kind, the set of all parameters corresponding to an optimal solution of parametric convex programming problems (or to an efficient solution of vector optimization problem (VOP)). Furthermore the STEP method given in (1) is an interactive scheme that profrssively elicits ingormation from the
decision maker primarily to modify the weights for solving multiobjective linear programming problems. Also in [3]. Hairs gave necessary and sufficient condition for the determination of the efficient solutions for (VOP) using the Hybrid approach which combiens the characteristics of bothe the nonnegative weighted sum problems and the $k$-th objective $\varepsilon$-constraints problem. And in [2], Bowman determine necessary and sufficient conditions for the determination of the efficient solutions for (VOP) using the generalized Tchebycheff norm. Also, Osman et al. in [9] introduced a modefied Hybrid approach for solving (VOP).

In this paper, an algorithm for determinig the stability set of the first kind for vector optimization problems with parameters in both the objective functions and in the constraints using interactive approaches is given.

## 2. PROBLEM FORMULATION

Let us consider the following parametric multiobjective nonlinear programming problem:

$$
\begin{array}{ll} 
& \min \left\{\left(f_{1}(x, \lambda), \ldots, f_{m}(x, \lambda)\right\}\right. \\
P(\lambda, v) \quad & \text { subject to } \\
& M(v)=\left[x \in R^{n} / g_{r}(x, v) \leq 0, r=1,2, \ldots, k\right]
\end{array}
$$

where $f_{j}, j=1,2, \ldots, m$ and $g_{r}, r=1,2, \ldots, k$ are convex functions of class $C^{(1)}$ on $\mathrm{R}^{\mathrm{n}}$, and $\lambda \varepsilon \mathrm{R}^{\mathbf{l}}, v \varepsilon \mathrm{R}^{\mathrm{k}}$ are vector parameters.

Let us define the following scalarization of $P(\lambda, v)$ which will be called the modified Hybrid approach.

$$
\mathrm{f}_{\mathrm{j}}(\mathrm{x}) \leq \varepsilon_{\mathrm{j}}, \mathrm{j}=1,2, \ldots, \mathrm{~m}
$$

whers $\bar{f} \in R^{m}$ is an ideal target, $\bar{f}_{j}=\min _{x \in M(v)} f_{j}(x, \bar{\lambda})$, and $w \in R_{+}^{m}$ (the positive orthant of the $\mathrm{R}^{\mathrm{m}}$ - space). It will be seen that the noninferior solutions of $P(\lambda, v)$ can be characterized in terms of the optimal solution of $P(\lambda, v)$ can be characterized in terms of the optimal solution of $P(\lambda, v, \varepsilon)$.

The problem $\mathrm{P}(\lambda, v, \varepsilon)$ can be reformulated to take the following equivalent form :

## $\operatorname{nim} z$

$\overline{\mathrm{P}}(\lambda, v, \varepsilon)$ subject to

$$
\begin{aligned}
N(\lambda, v, \varepsilon) & =\left\{(x, z) \in R^{n+1} / w_{j}\left[f_{j}(x, \lambda)-\bar{f}_{j}\right]-z \leq 0, f_{j}(x)-\varepsilon_{j} \leq 0\right. \\
. j & \left.=1,2, \ldots, m \text { and } g_{r}(x, v) \leq 0, r=1,2, \ldots, k,\right\}
\end{aligned}
$$

where $Z \in R$
It must be noted that roblem $\bar{P}(\lambda, v, \varepsilon)$ can be written in the equivalent form [3]:

$$
\min \left[f_{k}(x, \lambda)-\bar{f}_{k}\right]
$$

$\overline{\mathrm{P}}_{\mathrm{k}}(\lambda, \nu, \varepsilon)$ subject to

$$
\begin{gathered}
N_{k}(\lambda, v, \varepsilon)=\left\{(x, \lambda) \in R^{n+1} / w_{i}\left[f_{i}(x, \lambda)-\bar{f}_{i}\right]-f_{k}(x, \lambda)+\bar{f}_{k} \leq 0\right. \\
i=1,2, \ldots, m, i \neq k, f_{j}(x)-\varepsilon_{j} \leq 0, j=1, \ldots, m, \quad g_{r}(x, v) \leq 0 \\
r=1,2, \ldots, k\}
\end{gathered}
$$

which is obtained by eleminating $z$ from the first constraint of problem $\bar{P}(\lambda, v, \varepsilon)$.

Definition 1: The set of feasible parameters of problem $\bar{P}_{\mathbf{k}}(\lambda, v, \varepsilon)$ is defined by $\quad \mathrm{U}=\left\{(\lambda, \nu, \varepsilon) \varepsilon \mathrm{R}^{1+\mathrm{n}+\mathrm{k}} / \mathrm{N}_{\mathrm{k}}(\lambda, v, \varepsilon) \neq \varnothing\right\}$

Definition 2: the solvability set of problem $\mathrm{P}(\lambda, v, \varepsilon)$ is defined by

$$
B=\{(\lambda, v, \varepsilon) \in U / P(\lambda, v) \text { has efficient solution }\}
$$

Definition 3 : Assume that the problem $\mathrm{P}_{\mathbf{k}}^{-}(\lambda, v, \varepsilon)$ is solvable for $(\hat{\lambda}, \widehat{v}, \hat{\varepsilon})$ with a corresponding optimal point $(\widehat{x}, \hat{z})$, then the stability set of the first kind corresponding to $(\hat{x}, \hat{z})$ which is denoted by $S(\hat{x}, \hat{z})$ is defined by

$$
S(\hat{x}, \hat{z})=\left\{(\lambda, v, \varepsilon) \in B / \hat{z}=\underset{\left.(\hat{x}, \hat{z}) \in \min _{N_{k}(\lambda, v, \varepsilon)}\left[f_{k}(x, \lambda)-\bar{f}_{k}\right]\right\}}{ }\right.
$$

## 3. KUHM-TUCKER CONDITIONS AND STABILITY NOTION

From the assumption that the functions $f_{j}, j=1, \ldots, m$ and $g_{r}, r=1,2, \ldots, k$ are convex on $\mathrm{R}^{\mathrm{n}}$ and differentiable, then there exist

$$
\hat{\lambda} \in R^{1}, \hat{\mu} \in R^{m} \text { and } \hat{v} \in R^{k} \text { such that }(\hat{\mathbf{x}}, \hat{z}) \text { solves the following }
$$

## Kuhn-Tucker problem :

$$
\begin{align*}
& \frac{\partial f_{k}}{\partial x_{\alpha}}\left(\widehat{x}, \hat{\lambda}^{\prime}\right)+\frac{\Sigma}{j \neq k} u_{j} w_{j} \frac{\partial f_{k}}{\partial x_{\alpha}}\left(\widehat{x}, \hat{\lambda}_{j}\right)+ \\
& \sum_{i=1}^{m} \mu_{i} \frac{\partial f_{k}}{\partial x_{\alpha}}(x)+\sum_{r \in S} v_{r} \frac{\partial g_{r}}{\partial x_{\alpha}}\left(\bar{x}, \overline{v^{\prime}}\right)=0, \alpha=1, \ldots, n \tag{1}
\end{align*}
$$

$$
\begin{equation*}
\Sigma u_{j}=1 \tag{2}
\end{equation*}
$$

$-\mathrm{z}+\mathrm{w}_{\mathrm{j}}\left[\mathrm{f}_{\mathrm{j}}(\overline{\mathrm{x}}, \bar{\lambda})-\overline{\mathrm{f}}_{\mathrm{j}} \leq \mathrm{o}, \quad \mathrm{j}=1, \ldots, \mathrm{~m}, \mathrm{j} \neq \mathrm{k}\right.$
$\mathrm{f}_{\mathrm{i}}(\widehat{\mathrm{x}})-\ddot{\varepsilon}_{\mathrm{i}} \leq \mathrm{o}, \quad \mathrm{i}=1, \ldots, \mathrm{~m}$
$g_{r}(\hat{x}, \hat{v})<0 r \in S \subset\{1, \ldots, k\}$

$$
\begin{equation*}
\mathrm{g}_{\mathrm{r}}\left(\widehat{x}, \hat{\mathrm{v}}_{\mathrm{r}}\right)=0, \quad \mathrm{k} \notin \mathrm{~S} \tag{5}
\end{equation*}
$$

$$
\begin{align*}
& u_{j}\left\{-z+w_{j}\left[f_{j}(\hat{x}, \hat{\lambda})-\bar{f}_{j}\right]\right\}=0, j=1, \ldots, m, j \neq k  \tag{7}\\
& \mu_{j}\left[f_{j}(\bar{x})-\widehat{\varepsilon_{j}}\right]=0, \quad j=1, \ldots, m
\end{align*}
$$

$\mu_{\mathrm{j}}, \mathrm{u}_{\mathrm{j}}, v \geq \mathrm{o} \quad \forall \mathrm{i}, \mathrm{j}, \mathrm{r}$.
In order to find the stability set $\mathrm{S}(\hat{\mathrm{x}}, \hat{\mathrm{z}})$, let us consider the following set :

$$
\begin{align*}
& T=\left\{(I, J, S) / u_{j}=0, j \in J \subset\{1, \ldots, m\}\right. \\
& \mu_{i}=0, i \in I \subset\{1, \ldots, n\}, \\
& v_{r}=0, r \in S \subset\{1, \ldots, k\} \\
& \left\{u_{j}>0, j \notin J, \mu_{i}>0, i \notin I, \text { and } v_{r}>0, r \notin S\right\}  \tag{10}\\
& \text { then the set } S(\widehat{x}, \hat{z}) \text { takes the form : }
\end{align*}
$$

$$
\begin{aligned}
& S(\hat{x}, \hat{z})=S_{(I, J, S)}(\hat{x}, \hat{z}) \\
& =\left\{\left(\lambda, v, \varepsilon \in R^{\left.1+m / w_{j}(\bar{x}, \lambda)-\bar{f}_{j}\right] \leq \hat{z}, j \notin J}\right.\right.
\end{aligned}
$$

$$
\begin{aligned}
w_{j}\left[f_{j}(\widehat{x}, \lambda)-\bar{f}_{\mathrm{j}}\right] & =\hat{z}, j \notin J, \\
w_{j}\left[f_{j}(\widehat{x}, \lambda)-\bar{f}_{\mathrm{j}}\right] & =\hat{z}, j \notin J,
\end{aligned}
$$

It is well

$$
\begin{equation*}
\left.\mathrm{g}_{\mathrm{r}}(\hat{\mathrm{x}}, v) \leq \mathrm{o}, \mathrm{r} \in \mathrm{~S} \text { and } \mathrm{g}_{\mathrm{r}}(\hat{\mathrm{x}}, v)=0, \mathrm{r} \notin \mathrm{~S}\right\} \tag{11}
\end{equation*}
$$

known that
if $(\widehat{x}, \hat{z})$ is an optimal solution of $P(\lambda, v, \varepsilon)$ and $(\hat{x}, \hat{z}, \hat{u}, \hat{\mu}, \hat{v})$
solves the kuhn-Tucker conditions (1)-(9), where $u_{j}>0, \mu_{j}$
$>0, v_{k}>0$ and $f_{j}$ are strictly convex function on $R^{n}$, then $x$ is an efficient solution of $P(\lambda, v)$.

## 4. INTERACTIVE WITH THE DM TO ELICIT PREFERENCE

This method modifies.
i) the constraint set of $P_{k}(\lambda, v, \varepsilon)$, and
ii) the weights $w_{j}$ from the formula

$$
\begin{equation*}
w_{j}=\frac{f_{j}^{*}-\bar{f}_{j}}{\sum_{j \neq k} f_{j}^{*}-\bar{f}_{j}}, \tag{12}
\end{equation*}
$$

wher $f_{j}^{*}=\max _{x \in M\left(v^{*}\right)} f_{j\left(x, \lambda^{*}\right)}$ and $\bar{f}_{j}=\min _{x \in M\left(v^{*}\right)} f_{j}\left(x, \lambda^{*}\right)$.
At the r -th iteration, the DM is asked to evaluate the solution at the $(\mathrm{r}-1)$-th iteration, and to compare the values $f_{j}\left(x^{r-1}\right), \ldots, f_{m}\left(x^{r-1}\right)$ with the ideal $f_{1}^{*}, \ldots, f_{m}^{*}$.

He is asked to indicate which objective can be increased and by how much, so that other objective can be decreased from the current unsatisfactory levels. Suppose the DM chooses to sacrifice the $\hat{j} \neq k$ objective $f_{j}$ by $\Delta f_{j}$. The constraint set for the r -th iteration is

$$
\begin{equation*}
M^{T}=M^{i} \cap \bar{M}^{\mathrm{T}}, \tag{13}
\end{equation*}
$$

wiare

$$
\begin{align*}
& \bar{M}^{r}=\left\{x \in M\left(v^{*}\right) / f_{j}(x) \leq f_{k}\left(x^{r-1}\right)+\delta f_{j}\right. \\
& f_{k}(x) \leq f_{k}\left(x^{r-1}\right),+\hat{\lambda}_{k j}^{0} \delta f_{j}^{e} \\
& f_{l}(x) \leq f_{1}\left(x^{r-1}\right), 1 \neq k, \hat{j}, \delta f_{j}>0 \\
& \text { and } \quad f_{l}(x) \leq \epsilon_{l}^{0} \\
&\left.f_{j}(x) \leq \epsilon_{j}^{0}+\delta f_{j}, \quad j \neq \hat{j}, k\right\} \tag{14}
\end{align*}
$$

The weights should be modified accordingly setting

$$
\begin{equation*}
w_{j}=o \text { and } w_{j}=\frac{f_{j}^{*}-\overline{\mathrm{f}}_{\mathrm{j}}}{\sum_{\mathrm{i} \neq \mathrm{j}, \mathrm{k}} \mathrm{f}_{\mathrm{j}}^{*}-\overline{\mathrm{f}}_{\mathrm{j}}} \tag{15}
\end{equation*}
$$

consequently, the programming problem $\mathrm{P}(\lambda, v, \varepsilon)$ to be solved at the $r$-th iteration is

$$
\begin{equation*}
\min \quad z . \tag{16a}
\end{equation*}
$$

s.t. $w_{i}\left[f_{i}(x, \lambda)-f_{i}\right]-z \leq 0, i=1,2, \ldots, m, i \neq k, \hat{j}$,

$$
\mathrm{f}_{\mathrm{j}}(\mathrm{x})-\varepsilon_{\mathrm{j}} \leq 0, \mathrm{j}=1,2, \ldots, \mathrm{~m}
$$

$\mathrm{g}_{\mathrm{r}}(\mathrm{x}, \mathrm{v}) \leq 0, \quad \mathrm{r}=1,2, \ldots, \mathrm{k}$.
The process terminates when one of the following occurs:
i) the DM is satisfied with the current solution,
ii) there is no satisfactory objective in the current solution; or
iii) when $\mathrm{r}=\mathrm{n}$

## 5. THE ALGORITHM

Step 1: Asking the $D M$ to select any $\left(\lambda_{1}^{*}, v_{1}^{*}\right) \in U \quad$ to obtain an efficient solution $\quad x_{1}^{*}$ of $P(\lambda, v)$. Also, selects $f_{k}$ as a primary objective.

Step 2 : Compute the initial set of weights $w_{1}, \ldots, w_{m}$, set $r=1, M^{r}=M$.
Step 3: Asking the DM to select $\varepsilon_{j}^{1}$, where each $\varepsilon_{j}^{1} \quad$ should be selected in the range $\left[a_{j}, b_{j}\right]$ where

$$
a_{j}=\min _{x \in M\left(v_{1}^{*}\right)} f_{j}\left(x, \lambda_{1}^{*}\right), b_{j}=\max _{x \in M\left(v_{1}^{*}\right)} f_{j}\left(x, \lambda_{1}^{*}\right)
$$

Step 4: Formulate (16a) - (16d) and solvo to obtain $x_{1}^{*}$, Then compute $\mathrm{f}_{1}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right), \ldots, \mathrm{f}_{\mathrm{m}}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right)$.

Step 5 : Using (10) and (11) to obtain the set of all parameters corresponding to $\mathrm{x}_{\mathrm{j}}^{*}$.
Step 6 : Asking the $D M$ to compare $f_{1}\left(x_{1}^{*}, \lambda_{1}^{*}\right), \ldots, \mathrm{f}_{\mathrm{m}}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right)$ with $\overline{\mathrm{f}}_{1}, \ldots, \overline{\mathrm{f}}_{\mathrm{m}}$
(a) If the DM is satistfied with the current solution, stop-the best-compromise has been found.
(b) If there is no satisfactory objective, stop-no best-compromise solution can be found by this method.
(c) If there are some satisfactory objective, ask the DM to select one such objective $\hat{f}_{\hat{j}}$ and the amount $\delta f_{j}$ to be sacrificed (increased) in exchange for an improvement of some unsatisfactory objective.

Step 7: If $\mathrm{r}=\mathrm{n}$, stop-no best-compromise solution can be found by this method.

Otherwise set $\mathbf{r}=\mathbf{r}+1$, compute $\mathrm{M}^{\mathbf{r}}$, and modify the set of weights according to (13), (14) and (15), respectively. Then go to step 1 , where

$$
\left(\lambda_{2}^{*}, v_{2}^{*}\right) \notin S\left(\hat{x}_{j}, \hat{z}_{1}\right)
$$

Step 8: Analyzing the DM, and bathing through the questions qu. 1 and qu. 2 (Appendix (A)), one would expect that the solution $x^{\mathrm{r}+1}$ of a new problem $\bar{P}_{k}\left(\lambda_{\mathrm{I}}^{*}, V_{\mathrm{I}}^{*}, \varepsilon^{r}\right)$, where
$\varepsilon_{1}^{\mathrm{r}+1}=\varepsilon_{1}^{\mathrm{r}}-\delta \mathrm{f}_{\mathrm{l}}$ and $\varepsilon_{\mathrm{j}}^{\mathrm{r}+1}=\varepsilon_{\mathrm{j}}^{\mathrm{r}}+\delta \mathrm{f}_{\mathrm{j}}$,

$$
\left(\delta f_{j}>0 \text { and } \delta f_{l}>0\right)
$$

would be a better point than $x^{r}$ according to the DM stop.

## 6. MUMERICAL EXAMPLE

Let us consider the following problem :

$$
\min \left(f_{1}(x, \lambda), f_{2}(x, \lambda), f_{3}(x, \lambda)\right.
$$

subject to
$x_{1}+x_{2}-v \leq 2$ and $x_{1}, x_{2} \geq 0$,
where

$$
\begin{aligned}
& \mathrm{f}_{1}(\mathrm{x}, \lambda)=\lambda_{1}\left(\mathrm{x}_{1}-3\right)^{2}+\lambda_{2}\left(\mathrm{x}_{2}-2\right)^{2} \\
& \mathrm{f}_{2}(\mathrm{x}, \lambda)=\lambda_{1} \mathrm{x}_{1}+\lambda_{2} \mathrm{x}_{2} \\
& \mathrm{f}_{3}(\mathrm{x}, \lambda)=\lambda_{1} \mathrm{x}_{1}+2 \lambda_{2} \mathrm{x}_{2}, \text { and } v \in[0,1]
\end{aligned}
$$

Step 1 : Asking the DM to select $\left(\lambda_{1}^{*}, v_{1}^{*}\right)=(1,1,1, \ldots \in U$ to obtain an efficient solution $\mathrm{x}_{1}^{*}$, also select $\mathrm{f}_{1}$ as a primary objective.

Step 2 : The original set of weights computed from (12) is $w_{2}=1 / 3, w_{3}=2 / 3$,
and the $D M$ select $\varepsilon^{1}=(7,2,4)$.
Step 3: We solve the problem $\bar{P}_{1}\left(\lambda_{1}^{*}, v_{1}^{*}, \varepsilon^{1}\right)$, which yields the solution

$$
\begin{aligned}
& \hat{\mathrm{x}}_{1}^{*}=(0.4,1.6), \\
& \overline{\mathrm{z}}_{1}=0.67, \mathrm{f}_{1}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right)=6.9, \mathrm{f}_{2}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right)=2 \\
& \text { and } \mathrm{f}_{3}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right)=3.6 .
\end{aligned}
$$

Step 4 : Using (10) and (11) to obtain the set of all parameters $S\left(\hat{x}_{1}^{*}, \hat{z}_{1}\right)$
where $I=\{3\}, j=\{1,3\}, \quad S=\phi$

$$
\begin{gathered}
\mathrm{S}\left(\mathrm{x}_{1}^{*}, \hat{z}_{1}\right)=\mathrm{U}_{(\mathrm{I}, \mathrm{~J}, \mathrm{~S})}^{U} \mathrm{~S}\left(\hat{\mathrm{x}}_{1}^{*}, \hat{\mathrm{z}}\right) \\
=\left\{(\lambda, v, \varepsilon): 6.7 \lambda_{1}+0.16 \lambda_{2} \leq 2.67\right. \\
0.4 \lambda_{1}+3.2 \lambda_{2} \leq 0.96 \\
\varepsilon_{3} \leq 1.6,0.4 \lambda_{1}+1.6 \lambda_{2}=2.33 \\
\left.\varepsilon_{1}=6.9, \varepsilon_{2}=2, v=0\right\} .
\end{gathered}
$$

Step 5 : Suppose the DM compares $\mathrm{f}_{1}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right), \mathrm{f}_{2}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right), \mathrm{f}_{3}\left(\mathrm{x}_{1}^{*}, \lambda_{1}^{*}\right)$
with the ideal $(2,0,0)$ and is willing to give up (increase) $f_{2}$ by one unit from 2 to 3 to improve $f_{1}$, and then compute

$$
\lambda_{12}^{1}=-\left.\frac{\partial f_{1}}{\partial f_{2}}\right|_{x_{1}^{*}} ^{*}=9.6
$$

Step 6 : The new constraints set $M^{2}$ becomes

$$
\mathrm{M}^{2}=\mathrm{M}^{1} \cap \mathrm{M}^{2}=\mathrm{M} \cap \overline{\mathrm{M}}^{2}(\mathrm{v}),
$$

where

$$
\overline{\mathrm{M}}^{2}(v)=\left\{x \in R_{+}^{2} /\left(x_{1}-3\right)^{2}+\left(x_{2}-2\right)^{2} \leq 16.5,\right.
$$

$$
\begin{aligned}
& x_{1}+x_{2} \leq 3, x_{1}+2 x_{2} \leq 3.6 \text { and } \\
& x_{1}+x_{2}-v \leq 2, x_{1}+2 x_{2} \leq 5 \\
& \left.\left(x_{1}-3\right)^{2}+\left(x_{2}-2\right)^{2} \leq 7\right\}
\end{aligned}
$$

Take $w_{2}=0 \Rightarrow w_{3}=1$ and select $\left(\lambda_{2}^{*}, v_{2}^{*}\right), \notin S\left(\widehat{x}_{1}^{*}, \hat{\mathrm{z}}_{1}^{*}\right)$

$$
\text { where } \quad \lambda_{2}^{*}=(2.2), v_{2}=\frac{1}{2} .
$$

Step 7: We solve $\quad \min z$

$$
\begin{array}{ll}
\text { s.t. } & x \in M^{2}, 2 x_{2}+x_{2} \leq z \\
& 2\left(x_{1}-3\right)^{2}+2\left(x_{2}-2\right)^{2}-4 \leq z
\end{array}
$$

which yields $\mathrm{x}_{2}^{*}=(1.4,1.1), \hat{z}_{2}=7.2$ and

$$
\mathrm{f}_{1}\left(\mathrm{x}_{2}^{*}, \lambda_{2}^{*}\right)=22.64, \quad \mathrm{f}_{2}^{*}=5, \quad \mathrm{f}_{3}=7.2 .
$$

Step 8: The set of all parameters corresponding to $\left(\widehat{\mathrm{x}}_{2}^{*}, \hat{\mathrm{z}}_{2}^{*}\right)$, where
$\mathrm{I}=\{1,2,3\}, \mathrm{J}=\{1,2\}, S=\{1\}$ takes the form

$$
\begin{aligned}
& S\left(\left(_{x_{2}}^{*}, \hat{z}_{2}\right)\right.=\underset{(I, J, S)}{U} S\left(\hat{x}_{2}^{*}, \hat{z}_{2}\right) \\
&=\left\{(\lambda, v, \varepsilon): 1.4 \lambda_{1}+2.2 \lambda_{2}=7.2,\right. \\
&\left.\varepsilon_{1} \geq 3.37, \quad \varepsilon_{2} \geq 2.5, \quad \varepsilon_{3} \geq 3.6 \text { and } n \geq 0.5\right\} .
\end{aligned}
$$

## APPENDIX (A)

## Trade-off information [3].

Let $\lambda_{\mathrm{kj}}\left(\mathrm{x}^{\mathrm{o}}\right), \mathrm{j}=1,2, \ldots, \mathrm{~m}, \mathrm{j} \neq \mathrm{k}$ be the Kuhn-Tucker multipliers corresponding to the $\varepsilon$-constraints of $\overline{\mathrm{P}}_{\mathrm{k}}(\lambda, \nu, \varepsilon)$ where $\mathrm{x}^{0}$ solves $\overline{\mathrm{P}}_{\mathrm{k}}(\lambda, \nu, \varepsilon)$ : (i) If all $\lambda_{\mathrm{kj}}\left(\mathrm{x}^{0}\right)<0$ for each j , then the efficient surface in the objective space around the neighborhood of $f^{\rho}=F\left(x^{\circ}\right)$ can be represented by $f_{k}=f_{k}\left(f_{1}, \ldots, f_{k}\right.$, $\mathrm{f}_{\mathrm{k}+1}, \ldots, \mathrm{f}_{\mathrm{m}}$ ) and

$$
\lambda_{k j}\left(x^{\circ}\right)=-\left.\frac{\partial f_{k}}{\partial f_{j}}\right|_{F-F^{\circ}} \text { for each } j, j=1,2, \ldots, m, j \neq k \quad\left(A_{1}\right)
$$

Thus each $\lambda_{\mathrm{kj}}\left(\mathrm{x}^{\mathrm{O}}\right)$ represents the efficient partial trade-off rate between $\mathrm{f}_{\mathrm{k}}$ and $f_{j}$ at $F^{\circ}$ when all other objectives are held fixed at their respective values at $\mathrm{x}^{\mathrm{O}}$.
(ii) If $\lambda_{k j}\left(x^{0}\right)>0$ for some $j \neq k$ and $\lambda_{k l}\left(x^{\circ}\right)=0$, for some $I \neq k$, the efficient surface in the neighborhood of $F^{\circ}$ can then be expressed as $f_{k}=f_{k}(\widehat{F})$, where $\widehat{F}$ is a vector consisting of all $\mathrm{f}_{\mathrm{j}}$ with $\lambda_{\mathrm{kl}}\left(\mathrm{x}^{\circ}\right)>0$. Also, each $\lambda_{\mathrm{kl}}\left(\mathrm{x}^{0}\right)$ that is strictly positive can be interpreted as a trade-off rate, that exhibits an exchange between $f_{k}$ and $f_{j}$ while each objective $f_{l}$ such that $\lambda_{k l}\left(x^{0}\right)=0$ also changes. Thus if $\quad \lambda_{\mathrm{kI}}^{i}>0$ for each $1 \neq k$, then $\quad \lambda_{k l}^{i} \quad$ approximates a local partial trade-off at a point $x^{i}$ where $\lambda_{k l}^{i}$ is the Kuhn-Tucker multiplier associated with the constraints $f_{l}(x) \leq \varepsilon_{1}^{i}$. To move from $x^{i}$ to some other locally efficient point in the neighborhood of $x^{i}, \lambda_{k l}^{i}$ units of $f_{k}$ will be given up per one unit gain of $f_{1}$ (or vice versa), with all other objectives remaining constant at the level of $f_{l}\left(x^{i}\right), l \neq k$ and $j$ and therefore if $\lambda_{k l}^{k}>0$ for all $l \neq k$, we ask the DM for each $1 \neq k$ :
qu. 1: "given that $f_{j}=f_{j}\left(x^{i}\right)$ for all $j=1, \ldots, m$, how (much) would you like to decrease $f_{k}$ by $\lambda_{k 1}^{i}$ units for each one unit increase in $f_{1}$ will all other $f_{j}$ remaining unchanged ?".

If we make a smal change of $\delta \mathrm{f}_{\mathrm{j}}$ units in $\mathrm{f}_{\mathrm{li}}$ and setting $\mathrm{w}_{\mathrm{j}}=0$, where $l \in J_{\mathrm{n}}^{\mathrm{i}}=\left\{\mathrm{j} / 1 \leq \mathrm{j} \leq \mathrm{n}, \mathrm{j} \neq \mathrm{k}, \lambda_{\mathrm{kj}}>\mathrm{o}\right\}$, then $\mathrm{f}_{\mathrm{ki}}$ changes by - $\lambda_{\mathrm{k} 1}^{\mathrm{i}} \delta \mathrm{f}_{\mathrm{l}}$, and each $\mathrm{f}_{\mathrm{j}}$, where $\lambda_{\mathrm{kj}}=0$, also changes by $\lambda_{\mathrm{kl}}^{\mathrm{i}} \delta \mathrm{f}_{\mathrm{l}}$, and each $\mathrm{f}_{\mathrm{j}}$, where $\lambda_{\mathrm{kj}}=$ 0 , also changes by $\quad\left(\nabla \mathrm{f}_{\mathrm{j}}\left(\mathrm{x}^{\mathrm{i}}\right) \frac{\partial \mathrm{x}\left(\varepsilon^{\mathrm{i}}\right)}{\partial \varepsilon_{\mathrm{l}}}\right) \partial \mathrm{f}_{\mathrm{l}}$ units,
qu. 2 : Given that $f_{j}=f_{j}\left(x^{i}\right)$ for all $j=1, \ldots, m$, how (much) you like to decrease
$f_{k}$ by $\lambda_{k l}^{i}$ units and change $f_{j}$ by $\nabla f_{j}\left(x^{i}\right) \frac{\partial x\left(\varepsilon^{i}\right)}{\partial \varepsilon_{1}} \quad$ units, while increasing $f_{l}$
by one unit?.
